CFD Simulations of The ALICE L3, and ATLAS Muon Ventilation

Anna.Mueller@cern.ch

ALICE - THE PROBLEM

For the optimum operation of the detectors a stringent temperature uniformity is required.

We are looking for the solution of the air flow velocity and temperature field in a closed volume with the 17 kW of heat dissipated.

What is the best ventilation configuration ensuring the uniform temperature field in the air surrounding the detectors?

ALICE - THE MESH.

- The trimmed, nonuniform mesh was used,
- 1 milion of cells,
- 16 different configurations of inlets studied.

ALICE - THE MODEL

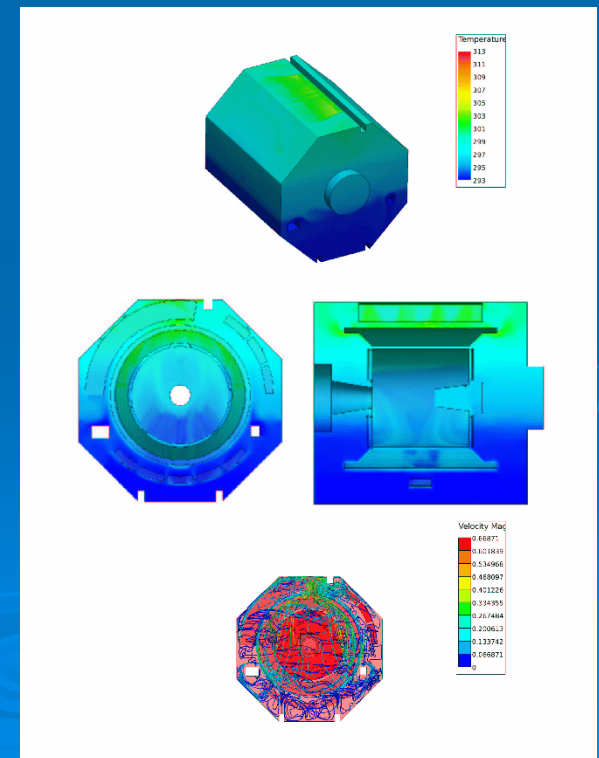

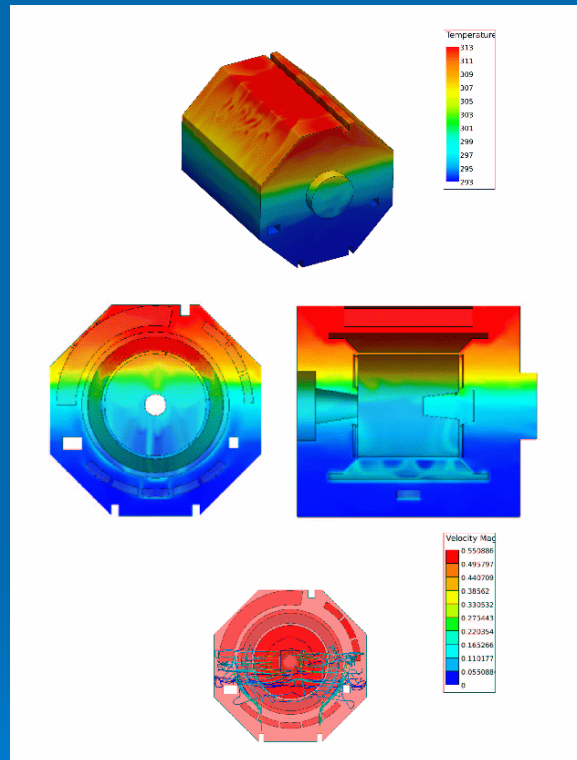

- 3D flow simulation,
 - Time dependent study (strong influence of natural convection)
 - Air treated as the ideal gas,
 - Turbulence modeled – k-epsilon,
 - Heat dissipation applied on subdetectors' outer surfaces – 17 kW,
 - Heat sink – L3 magnet thermal screen kept at constant temperature 293 K.
-
- There will be supplied 6000 m³/h of air at 293 K.
 - It is possible to install ventilating ducts in 5 to 6 positions, parallel to the beam pipe.

ALICE - RESULTS

For details see: EDMS 528133

ALICE - RESULTS

- Understanding the flow originated by the natural convection phenomena,
- Pointing the hot-spots located over the EMC detector,
- The best configuration (out of 16 tested) allowed to reduce the maximum temperature from 331K to 310 K

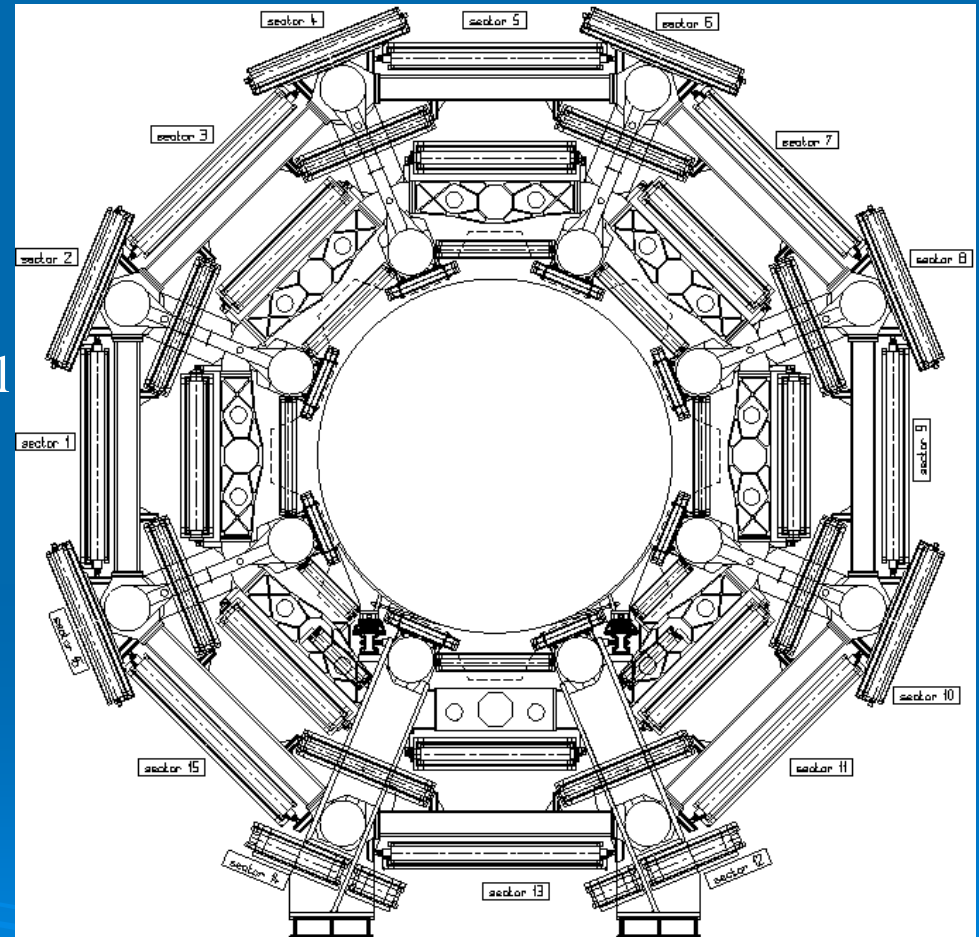

For details see: [EDMS 528133](#)

ATLAS – THE PROBLEM

- **80 kW** of heat is being dissipated from the Muon Chambers and the Calorimeter.
- The Cavern ventilation: 60000 m³/h of air at 17 C.
- The possibility of introducing the thermal screens kept at 20 C in the inner layer of sectors 3, 5 and 7.
- The resulting temperature and velocity field will be used for more detailed thermal study of chambers realised by RFNC-VNIITF – LLC Strela, Snezhinsk, Russia .

Diameter ~ 20 m

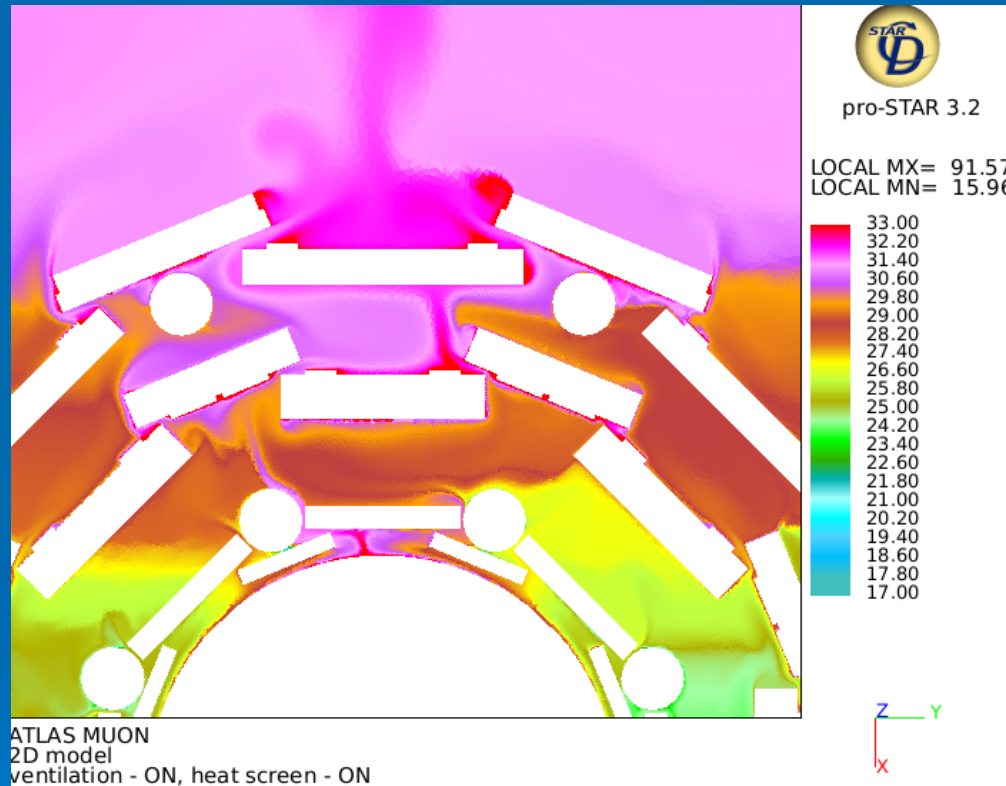

ATLAS – THE MODEL

2D model. 230000 cells.

ATLAS – THE RESULTS

Thermal screen takes away 2 % of heat dissipation in the volume

ATLAS – THE RESULTS

pro-STAR 3.2

TIME = 4.00000
LOCAL MX= 35.19
LOCAL MN= 17.00
